1. Project Overview

The Beuca Property is a proposed residential development consisting of single-family detached units. The Beuca Property project is located in Section 25, Township 26 North, Range 5 East, W.M, on the north side of NE 122nd Street and west of 166th Place NE (see Figure 1-1 - Vicinity Map). The project properties total 3.59 acres. The total area to be developed is 4.02 acres; this includes future frontage improvements. To the north, west and east of the site are single family residential areas. The south side of the project is bounded by NE 122nd Street. This project is located within the City of Redmond.

The proposed site consists of two parcels as follows:

Table 1-1	
KC Parcel #	Site Area (SF)
2526059029	110,642
2526059151	45,738

Drainage from the property sheet flows across adjacent properties to the west and south into an existing ditch and culvert system on the north side of NE 122nd Street that conveys the flows west toward NE 124th Street.

Proposed development of the property will include the demolition of all structures on the property and construction of 15 single-family units (1 duplex) on 14 lots, along with associated roadway, utilities, open space, and drainage detention and treatment. Frontage improvements along NE 122nd Street and 166th Place NE and ROW improvements within the offsite NE 123rd Place will also be included as part of the development.

A single detention vault will be located in Tract A near the southwest corner of the property and designed per Redmond's design criteria. The detained flows will then be conveyed west to NE 122nd Street and into the existing ditch system located on the north side of NE 122nd Street or into the proposed tight line pipe system to be constructed as part of the Shadow Creek development immediately west of the Beuca Property project.

Basic water quality treatment is provided through dead storage and is computed using the 6-month, 24-hour storm volume as determined using Water Works software. Flow control is provided with 9.2 feet of live storage and will match developed discharge durations to 50% of the pre-developed 2-year peak flow to the full 50-year peak flow as determined by King County Runoff Time Series (KCRTS).

Wellhead Protection Zone Limitations

The project site is within Wellhead Protection Zone 4, per the City of Redmond's Wellhead Protection Zone Map (see Figure 2-1).

HOME IMPROVEMENT EXEMPTION

New Search Property Tax Bill Map This Property Glossary of Terms Area Report Print Property Detail

2. Conditions and Requirement Summary

The proposed project is classified as a "Large Project" per Section 3.5, pg 57, within the City of Redmond Clearing, Grading, and Stormwater Management Technical Notebook, Issue No. 6 dated February 23, 2012 (Technical Notebook). Per Figure 3.2 (shown below) and Section 3.5, "all minimum requirements apply to the new impervious surfaces and converted pervious surfaces."

The City of Redmond Clearing, Grading, and Stormwater Management Technical Notebook, Issue Number 6 discusses wellhead protection within the City and corresponding restrictions and limitations.

Section 2.5.5, beginning on page 24 of the Technical Notebook, provides the following summary regarding **Groundwater Protection** in Wellhead Protection Zone 4:

"In Wellhead Protection Zone 4, runoff from pollution generating impervious surfaces can be infiltrated without treatment provided the soil profile provides treatment per Chapter 3.3 of Volume III of the 2005 Ecology Manual. Infiltration of runoff from non-pollution generating impervious areas considered to be clean, including most roofs and sidewalks, is strongly encouraged where feasible."

As noted above, infiltration is encouraged in Wellhead Protection Zone 4 provided the soil profile supports the applicable water quality treatment requirements.

Minimum Requirement #1: Preparation of Stormwater Site Plans: Preliminary Civil Plans under separate cover and Preliminary Storm Drainage Report herein have been prepared for the subject project. The proposed project is classified as a "Large Project" per Section 3.5, pg 57, within the Technical Notebook.

Minimum Requirement #2: Construction Stormwater Pollution Prevention: All new development and redevelopment shall comply with the Construction SWPPP Element #1 through Element #12 listed in the 2005 DOE Stormwater Manual. The Beuca Property project disturbs more than 7,000 square feet of land and will require a Construction SWPPP. Erosion/Sedimentation Control and Construction Stormwater Pollution Prevention Plans will be completed during final engineering design.

<u>Minimum Requirement #3: Source Control of Pollution</u>: RMC 13.06.066 requires that applicable adopted source control BMPs (operational and structural) be used on all sites except Single Family Residential sites. As this project is a Single Family Residential site Source Control BMPs do not apply.

Minimum Requirement #4: Preservation of Natural Drainage Systems and Outfalls:

Natural drainage patterns shall be maintained, and discharges from the project site shall occur at the natural location, to the maximum extent practicable. The manner by which runoff is discharged from the project site must not cause a significant adverse impact to downstream receiving waters and down gradient properties. Discharge from the site is to the existing natural discharge location. See Section 3 of this Report for the downstream analysis and discussion of the natural discharge location. The storm water runoff for the project site will be conveyed to the existing ditch system on the north side of NE 122nd Street or to the proposed tight line pipe system to be constructed as part of the Shadow Creek project.

All outfalls require energy dissipation. All outfalls will be designed with appropriately sized energy dissipation. See Section 4 of this report for further drainage basin analysis.

Minimum Requirement #5: On-Site Stormwater Management: Projects shall employ On-site Stormwater Management Best Management Practices (BMPs) to infiltrate, disperse, and retain stormwater runoff onsite to the maximum extent feasible without causing flooding or erosion impacts. Roof Downspout Control BMPs, functionally equivalent to those described in Chapter 3 of Volume III of the 2005 DOE Stormwater Manual, and Soil Quality BMPs, functionally equivalent to those in Chapter 5 of Volume V of the DOE Stormwater Manual, shall be required to reduce the hydrologic disruption of developed sites.

Per Figure 3.1 in Volume III Chapter 3 of the DOE Manual, roof downspouts should be connected to street drainage system with perforated stub-outs. For this project, the design for the perforated stub-outs apply to single family detached homes and requires a minimum setback of 25' from the utility trenches or foundation drains and 50' setback from any structure, property line, or steep slope per Section 2.9.3.3,

page 42, of the City of Redmond Technical Notebook. This cannot be accommodated for with the current site layout therefore, roof stubs will be solid PVC connected to the tight-lined storm drainage system.

Additional On-Site Stormwater Management BMPs per Section 8.7 of the Technical Notebook will be assessed and applied to the project site as appropriate during the final engineering phase of the project. This typically would include amending onsite soils with compost material to increase interflow runoff time.

Compost amended soil will be applied in landscape areas and will follow guidelines in Appendix Q of the 2012 (Issue #6) Redmond Stormwater Technical Notebook, "Guidelines for Landscaping with Compost-Amended Soils," the 2012 City of Redmond Standard Drawing #632, "Soil Amendment and Depth," or DOE BMP T5.13, "Post-Construction Soil Quality and Depth.".

<u>Minimum Requirement #6: Runoff Treatment:</u> The following require construction of stormwater treatment facilities (see Table 2.1 included below):

- Projects in which the total of pollution generating impervious surface (PGIS) is 5,000 square feet or more in a threshold discharge area of the project, or
- Projects in which the total of pollution-generating pervious surfaces (PGPS) is three-quarters (3/4) of an acre or more in a threshold discharge area, and from which there is a surface discharge in a natural or man-made conveyance system from the site.

This project results in a total of approximately 30,000 square feet of PGIS and therefore requires construction of a stormwater treatment facility.

Table 2.1 Treatment Requirements by Threshold Discharge Area							
	<3/4 acres of PGPS	>3/4 acres PGPS	<5,000 sf PGIS	>5,000 sf PGIS			
Treatment Facilities		Х		Х			
On-site Stormwater BMPS	Х	Х	Х	Х			

PGPS = pollution generating pervious surfaces

PGIS = pollution generating impervious surfaces

sf = square feet

Based on the <u>Treatment-Type Thresholds</u> in Section 2.5.6 of the Technical Notebook, the project site requires Basic Treatment. Design of the treatment facilities is described in Section 4 of this Report. Placement of the treatment facilities is shown on the Preliminary Civil Plans.

<u>Minimum Requirement #7: Flow Control</u>: Per Section 2.5.7 of the Technical Notebook, the following require construction of flow control facilities and/or land use management BMPs that will achieve the standard flow control requirement for western Washington (see Table 2.2 included below):

- Projects in which the total effective impervious surfaces is 10,000 square feet or more in a threshold discharge area; or
- Projects that convert ¾ acres or more of native vegetation to lawn or landscape, or convert 2.5 acres or more of native vegetation to pasture in a threshold discharge area, and from which there is a surface discharge in a natural or man-made conveyance system from the site; or

Projects that disturb one acre or more, that through a combination of impervious surfaces and
converted pervious surfaces cause a 0.1 cubic feet per second increase in the 100-year flow
frequency from a threshold discharge area as estimated using the Western Washington Hydrology
Model or other approved model.

Table 2.2 Flow Control Requirements	by Threshold D	ischarge Area
	Flow Control	On-site Stormwater
	Facilities	Management BMPs
<3/4 acres conversion to lawn/landscape, or <2.5 acres to pasture		Х
> 3/4 acres conversion to lawn/landscape, or > 2.5 acres to pasture	Х	Х
<10,000 square feet of effective impervious area per TDA		Х
>10,000 square feet of effective impervious area per TDA	Х	Х
>0.1 cubic feet per second increase in the 100-year flood frequency for sites 1 acre or larger	Х	Х

This project results in an excess of 10,000 square feet of effective impervious surfaces and therefore requires construction of a flow control facility.

Per Section 2.5.7 of the Technical Notebook, the <u>Standard Flow Control Requirements</u> applies with the pre-developed condition to be modeled as forested land cover. Stormwater discharges shall match developed discharge durations to pre-developed durations for the range of pre-developed discharge rates from 50% of the 2-year peak flow up to the full 50-year peak flow.

Design of the flow control facility is described in Section 4 of this Report. Placement of the flow control facility is shown on the Preliminary Civil Plans.

<u>Minimum Requirement #8: Wetlands Protection</u>: This requirement applies only to projects whose stormwater discharges into a wetland, either directly or indirectly through a conveyance system. There are no wetlands located on site or off site in proximity to the project. No additional protection measures are required.

Minimum Requirement #9: Operation and Maintenance: Per Section 2.5.9 of the Technical Notebook, an operation and maintenance manual that is consistent with the provisions in Volume V of the 2005 DOE Manual is required for all proposed public and private stormwater facilities including flow control and treatment facilities, conveyance systems, constructed source controls, and green infrastructure. The operations and maintenance manual shall be a stand-alone document prepared in accordance with the City of Redmond O&M Manual Template (see Appendix N of the Technical Notebook). The development proposal shall include provisions for maintenance of facilities in perpetuity.

The Operation and Maintenance Manual will be included at final design.

3. Off-Site Analysis

Upstream

See Section 4 of this Report for a description of the upstream area that will be considered upstream to the proposed detention/water quality treatment facility.

Downstream Resource Review

The following resources were reviewed in preparation of this report.

Redmond Sensitive Areas Maps

These maps were reviewed for *Erosion Hazard* (Map 64.8), *Wetlands* (Map 64.4), *Landslide Hazard* (Map 64.7), and *Seismic Hazard* (Map 64.9). The project site does not fall within or near any sensitive areas noted on the City Sensitive Area maps.

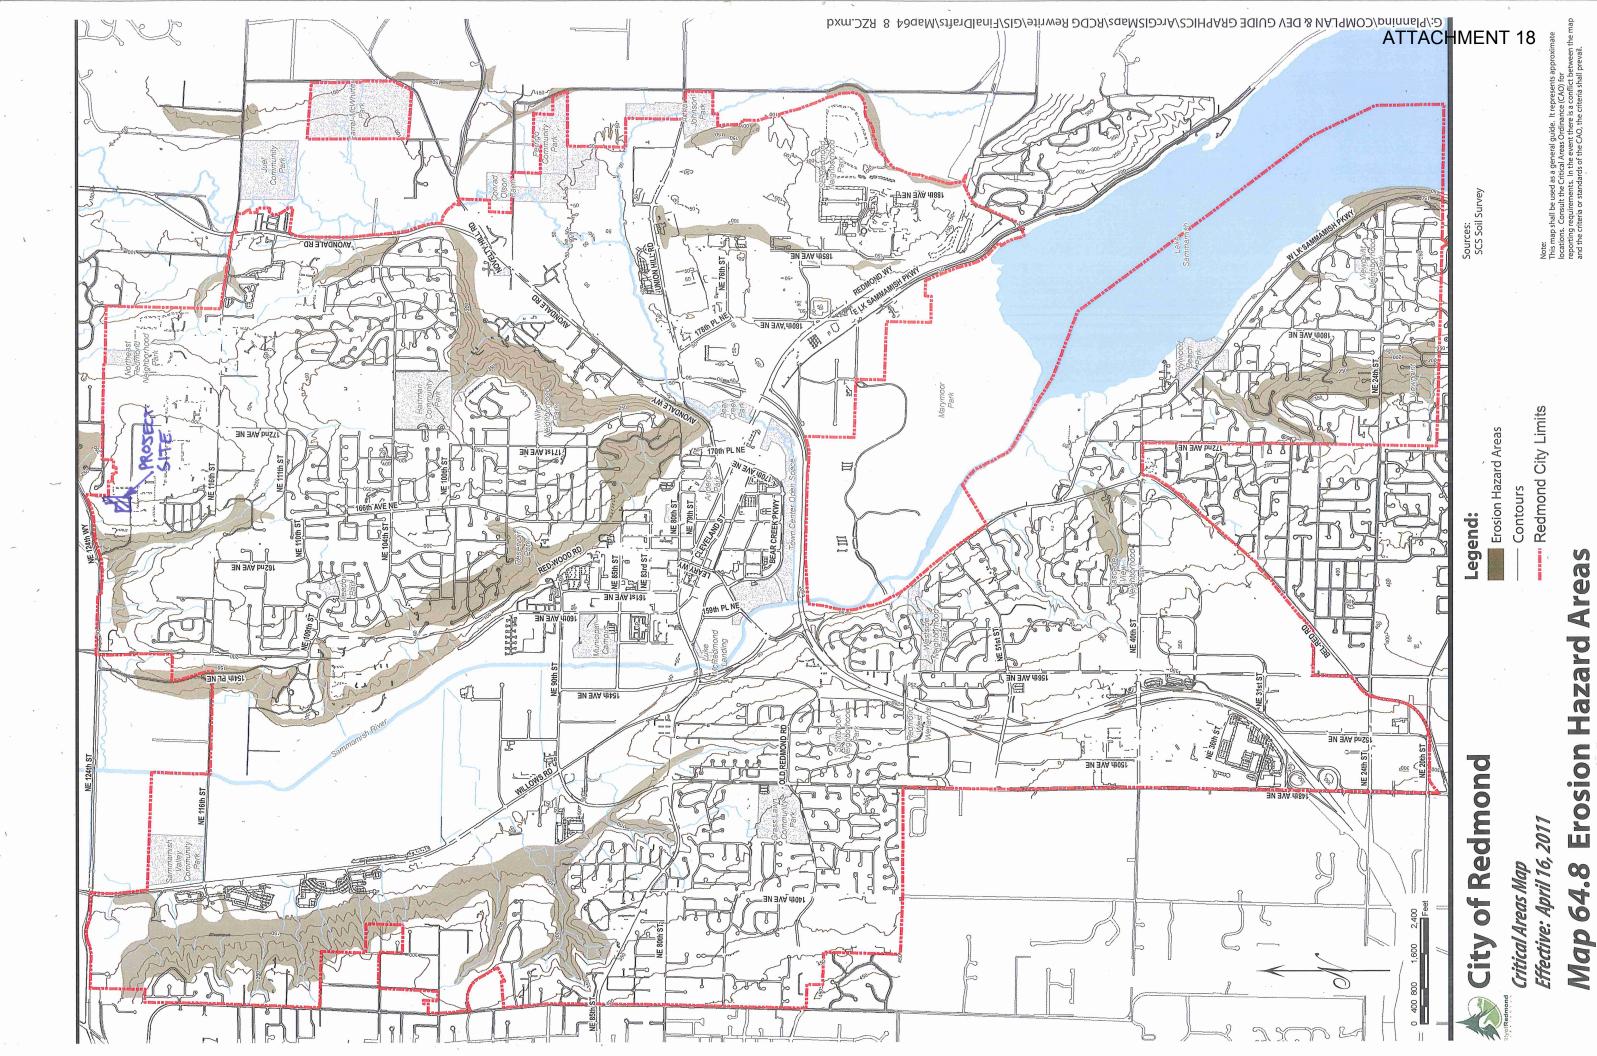

FEMA – Flood Insurance Rate Map (FIRM #53033C0380F)

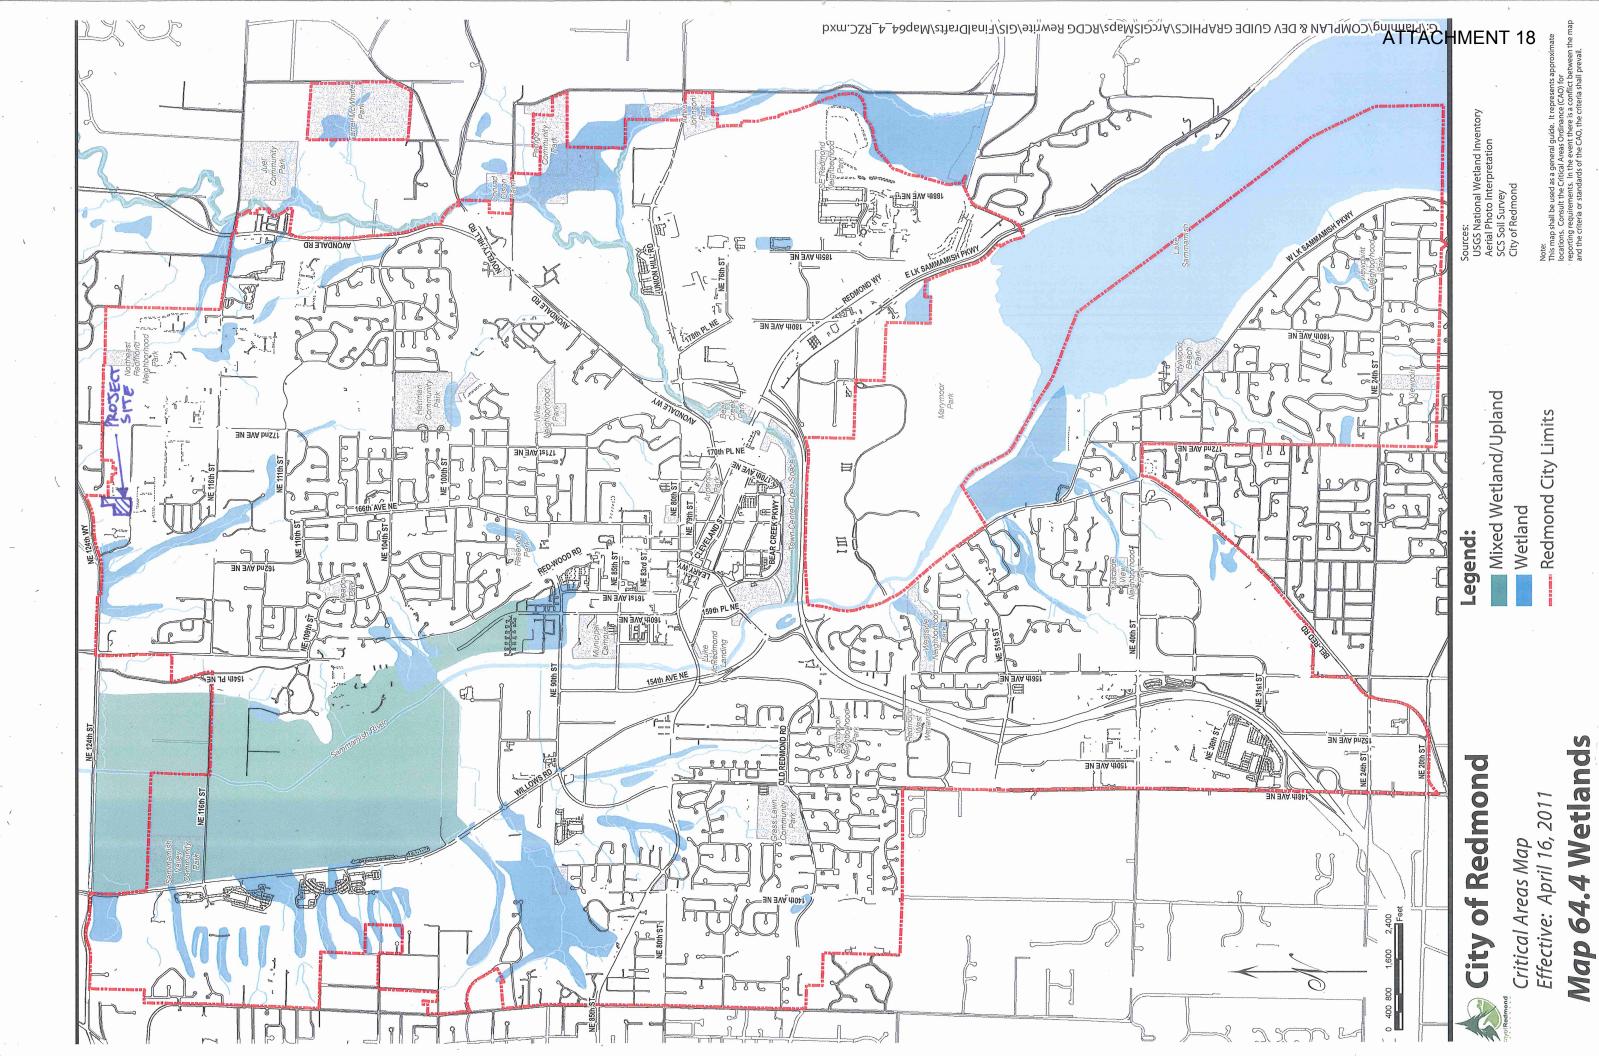

This panel is not available and is reported to be in Zone X, with no flood areas identified on or near the site. This was also confirmed on the City of Redmond Parcel Viewer online interactive GIS map system.

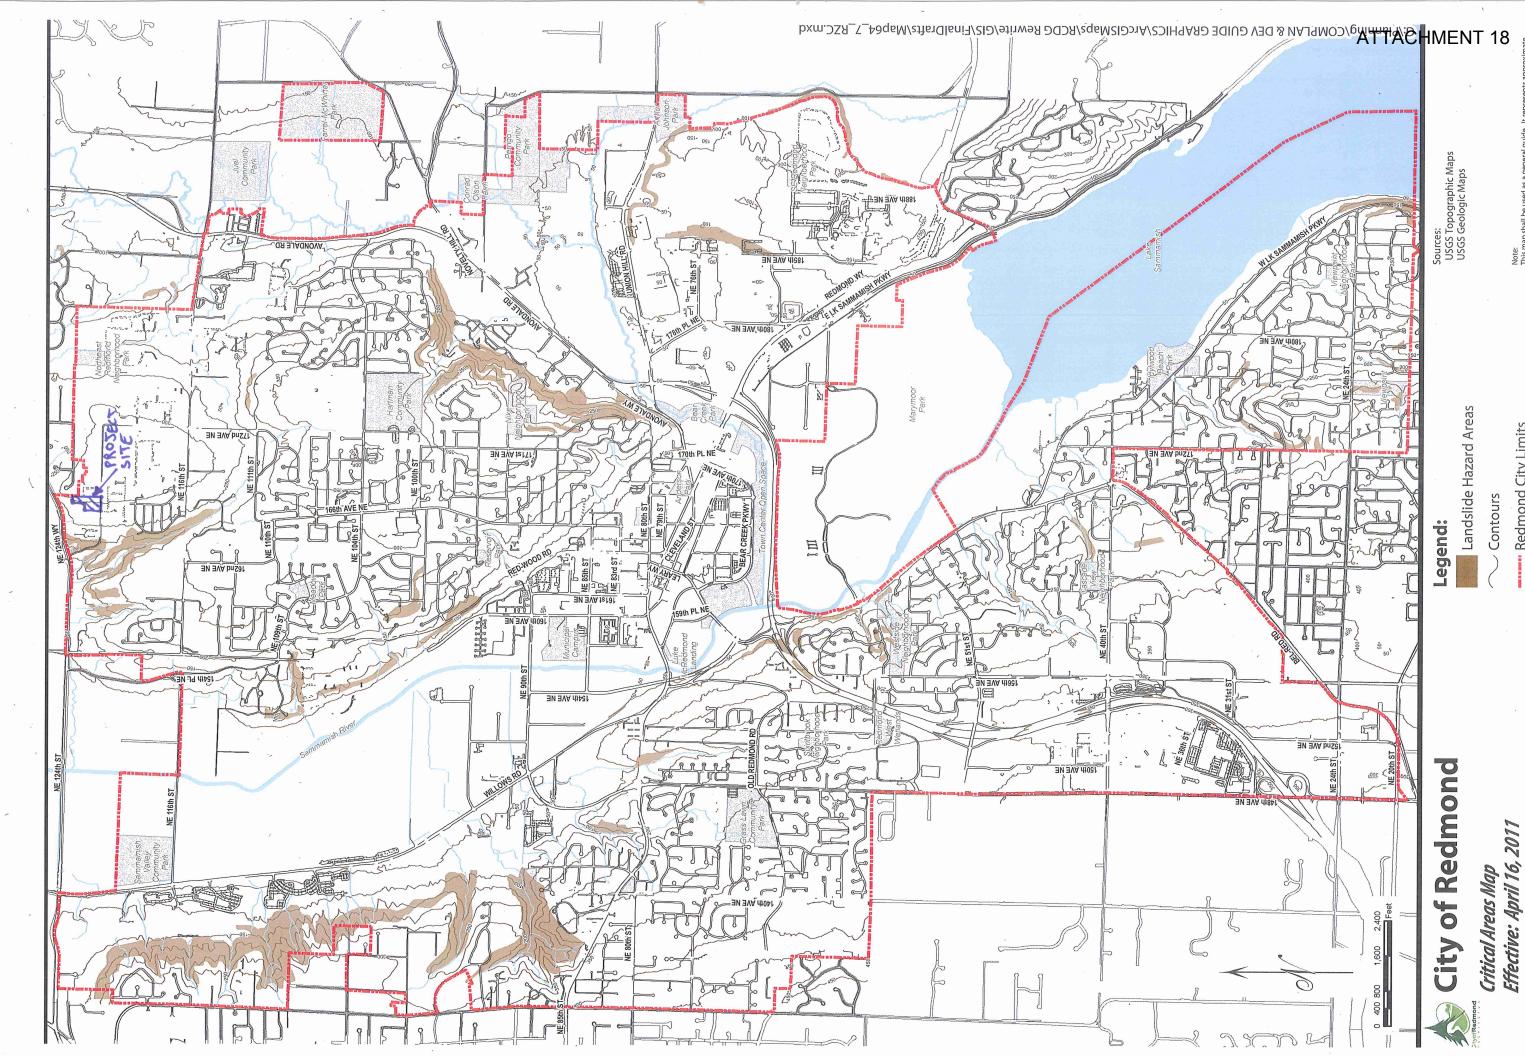

USDA Natural Resources Conservation Service Soil Survey

The soil for this property is classified as AgC (Alderwood gravelly sandy loam, 6 to 15 percent slopes) from the *Natural Resources Conservation Service Soil Survey*.

Downstream Field Investigation:

Date of Field Inspection: July 16, 2013 Weather Conditions: Sunny, 70° F

The existing topography of the site slopes from the northeast to the southwest across the adjacent properties to the west into the existing ditch that flows west on the north side of NE 122nd Street (please view the "Beuca Property Downstream Inspection" map that proceeds this downstream analysis. The exhibits mentioned in this investigation are located on the map, and their pictures follow). The ditch has a bottom width ranging between 1 and 2 feet, and is between 1 and 2 feet deep. The ditch is lined with a mixture of gravel, grass, dirt and sand. The drainage flows approximately 21 feet until it passes beneath a gravel driveway through a 12" concrete pipe that is 18 feet long. Both the pipe inlet and outlet are half filled with sediment, but there are no signs of flooding (see Exhibits A and B). The ditch continues 108 feet westerly until reaching another driveway in which the stormwater also flows through an 18 foot long 12" concrete pipe that has an inlet and outlet half filled with sediment (see Exhibits C and D). Maintenance on these concrete pipes is recommended. The ditch continues another 90 feet westerly until it reaches a third gravel driveway where the stormwater drains through a 27 foot long 12" concrete pipe, and the inlet and outlet are clear of any sediment as though the pipe has been properly maintained (see Exhibit E). The ditch continues about 8 feet westerly until it reaches a 12" plastic pipe with a vertical metal grate inlet (see Exhibit F). The pipe connects to a Type 1 catch basin 18 feet downstream that is part of a curb and gutter conveyance system (see Exhibit G). This curb and gutter system is a part of the recently built Woodlands Ridge housing development. The 12" plastic pipe runs westerly 57 feet until it reaches another Type 1 catch basin (see Exhibit H). Then, the stormwater continues westerly through another 12" plastic pipe to a third and final Type 1 catch basin 180 feet downstream. The third catch basin releases stormwater through an 18 foot long 12" plastic pipe to a ditch system (see Exhibit I). The ditch system is also on the north side of NE 122nd Street, and it has a bottom width of about 2 feet and a depth between 1 and 2 feet. The ditch continues west along the north side of NE 122nd Street as the roadway curves from heading east-west to north-south (see Exhibit J). About a third of the way through the turn, another 57 feet, the stormwater enters a 15" corrugated plastic pipe with a vertical metal grate inlet (see Exhibit K), and exits on the same side of the roadway into a ditch that has a bottom width of 2 feet and a top width of about 6 feet. At this point, the ditch becomes lined with riprap (see Exhibit L). This ditch continues along the east side of what is now 162nd Place NE. The stormwater is conveyed northerly until it flows through another 15" corrugated plastic pipe 190 feet downstream (see Exhibit M). This outlet of the pipe is 130 feet downstream where the stormwater exits into a ditch that is also lined with riprap for 90 feet, then becomes lined with tall grass (see Exhibit N). The ditch continues another 160 feet until it reaches the southeast corner of NE 124th Street and 162nd Place NE, where the drainage merges with stormwater flowing westerly down NE 124th Street. The downstream inspection from this point onward is described below, as part of the Cooper Property P.R.D. downstream analysis from June 2007. The Cooper Property downstream conveyance system characteristics were verified the same day as the downstream inspection above. The downstream analysis was based on field reconnaissance.

The following is taken from the Cooper Property P.R. D. downstream analysis dated June 2007 (revised May 2008).

Downstream:

Date of Field Inspection: December 7, 2006 Weather Conditions: Cloudy, mid 40° F

Drainage within the north-flowing ditch along 162nd Place NE concentrates all site drainage at the northwest corner of the [Cooper] property where it enters into an 18" culvert located at the southeast corner of the intersection of NE 124th Street and 162nd Place NE. Drainage is conveyed west through the 18" culvert under 162nd Place NE. On the southwest corner of the intersection of NE 124th Street and 162nd Place NE, the drainage was bubbling out of the ground, but no culvert exit could be located. It was assumed that the culvert exit was plugged due to sedimentation. The drainage continues west in a roadside channel located along the south side of NE 124th Street. At the driveway of 16215, the drainage enters a culvert, however the culvert exit could not be found. On the immediate west side of the driveway the ditch was dry. Approximately 50 feet further west on NE 124th Street, drainage reappears in the ditch. The drainage continues west in a grass-lined trapezoidal channel which is approximately one foot wide at the bottom, and is approximately three to four feet deep. Approximately 550 feet downstream from the subject site, the drainage in the ditch and another water course converge and cross north under NE 124th Street through a 42" CMP. In the event of a significant rainfall some of the drainage could continue west on the south side of NE 124th Street through an 18" CMP and a 24" CMP. These culvers have higher invert elevations than the 42" CMP, therefore it was concluded that the majority of the drainage would head to the north side of NE 124th Street. On the north side of NE 124th Street, the drainage turns west and is conveyed through a swale that is approximately six feet wide and three feet deep. This swale has a few weirs/drops intermediately spaced. There are several 36" concrete culverts placed along the channel at existing driveways. The swale appears to parallel NE 124th Street further to the west; however the field inspection was terminated at this point which was beyond ¼ mile downstream.

Based on field observations, there were no visible signs of erosion and/or flooding within the downstream system though signs of sedimentation within existing culverts were noted. An additional field reconnaissance was performed on Nov. 20, 2012, following record rainfall. The ditches were flowing ½ full with no erosion evident. The storm system at 162nd Place NE was flowing and didn't appear to be restricted in flow.

Exhibit M Exhibit N

Capacity Analysis:

The offsite ditch downstream (south) of the Beuca Property in Redmond, WA, was field verified on July 16, 2013 and calculated using Manning's equation for capacity. The weather was sunny and approximately 70° F. The offsite ditch is on the north side of NE 122nd Street and slopes down to the west, follows the curve to the north, then continues down to the north until it reaches the southeast corner of the intersection of NE 124th Street and 162nd Place. The ditch begins as naturally lined with a mixture of gravel, grass, dirt, and sand. The geometry of the ditch was field verified as approximately 220 feet long, between 1 and 2 feet deep, and between 1 and 2 feet wide at the bottom. The corresponding side slope on either side is 1.5H:1V. The ditch meets the new tight-lined conveyance system constructed as a part of the Woodlands Ridge housing development. Downstream of the Woodlands Ridge conveyance system is another naturally lined ditch. Midway through the turn from west to north, the naturally lined ditch empties into a larger ditched that has been reinforced with quarry rock as part of recent development activity. The geometry of the ditch was field verified as approximately 280 feet long, 2 feet wide at the bottom, and 7 feet wide at the top (maximum design flow depth). The corresponding side slope on either side is 2.5H:1V and the entire length of the ditch is rock lined.

Although topographic survey information was field verified as approximately 14%, a conservative assumption was used and 10% was chosen as the slope input for both ditches.

During the field visit it was noted that there is measurable flow into the culvert at the downstream end but that flow is not visible in the ditch itself due to the geometry and rock lining. For the rock-lined ditch, a conservative flow depth of 6" was chosen as a result to provide for anticipated ditch flow characteristics during high flow storm events, and to provide adequate freeboard. In this case, a maximum flow depth of 18" was measured in the field, providing a minimum freeboard of 12". For the naturally lined ditch, a

conservative flow depth of 6" was used, providing a minimum freeboard of 6". Because the geometry of the ditch varies along the flow path, minimums of a bottom width of 1 foot and a top width of 4 feet were used.

The 2009 King County Surface Water Design Manual was used to determine the methodology for calculating the conveyance capacity of both offsite ditches. The first calculation shown is for the naturally lined ditch, and the second calculation is for the rock-lined ditch further downstream. Section 4.4 (page 4-55) discusses open channels and specifically "Rock-lined channels" like the one the Beuca Property proposes to discharge to. Conveyance capacity may be calculated using Manning's equation, or Equation 4-2 (page 4-20) of the 2009 KCSWDM.

Naturally-lined Ditch Capacity Calculation:

$$Q = \frac{1.49}{n} A R^{2/3} S^{1/2}$$

Q = ditch capacity at design flow depth (6.99 cfs)

n = Manning's roughness coefficient (0.027 – Table 4.4.1.B)

A = area (0.875 sf – field verified, use Figure 4.4.1.E)

R = hydraulic radius = area / wetted perimeter ($0.31 \, ft$ – field verified, use Figure 4.4.1.E)

S = ditch slope (0.10 ft/ft - field verified, conservative)

 $y_1 = 0.5 ft - (6" flow depth assumption)$

b = 1.0 ft - (field verified)

z = 1.5 (field verified)

Using the field verified measurements for the offsite naturally-lined ditch, Manning's equation and corresponding design inputs the corresponding conveyance capacity of the ditch at 6" flow depth is 6.99 cfs.

Rock-lined Ditch Capacity Calculation:

$$Q = \frac{1.49}{n} A R^{2/3} S^{1/2}$$

Q = ditch capacity at design flow depth (9.5 cfs)

n = Manning's roughness coefficient (0.040 – Table 4.4.1.B)

A = area (1.63 sf – field verified, use Figure 4.4.1.E)

R = hydraulic radius = area / wetted perimeter (0.35 ft – field verified, use Figure 4.4.1.E)

S = ditch slope (0.10 ft/ft - field verified, conservative)

 $y_1 = 0.5 ft - (6" flow depth assumption)$

b = 2.0 ft - (field verified)

z = 2.5 (field verified)

Using the field verified measurements for the offsite rock-lined ditch, Manning's equation and corresponding design inputs the corresponding conveyance capacity of the ditch at 6" flow depth is **9.5** cfs.

In order to confirm adequate capacity in the offsite ditch, the conveyance capacity calculated above was compared to the anticipated detained flows contributing to the ditch from the upstream development area. The offsite ditch collects flows from upstream developments via the Prescott Glen pond, in addition to surface water from NE 122nd Street. Some of the upstream development on the north side of NE 122nd Street is routed to the south and into the Prescott Glen pond. The Sycamore Park, Wexford Glen, Thorn Property and Prescott Glen developments are all tributary to the Prescott Glen pond and discharge into the offsite ditch on the south side of NE 122nd Street before it crosses under the street and combines with flows from the north side of NE 122nd Street (after adding the Federspiel Property detained flows). The existing ditch on the east side of 162nd Avenue NE conveys flows from the entire tributary area on both sides of NE 122nd Street and therefore must be able to contain the 25 year release rates from all of the upstream stormwater facilities and any bypass areas not collected by the facilities.

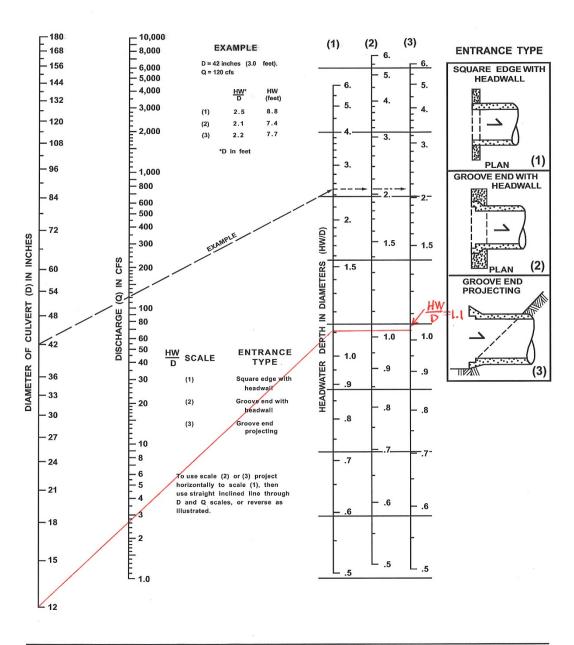

The proposed Thorn Property project includes all of the upstream areas mentioned except the Federspiel Property. The point of compliance is downstream of the pond and therefore includes bypass area as well related to full build out of NE 122nd Street. The corresponding 25 year discharge for the mitigated (detained) Thorn Property (modified Prescott Glen pond) point of compliance is 1.22 cfs. The corresponding 25 year discharge for the mitigated (detained) Federspiel Property point of compliance is 0.15 cfs. The total combined 25 year discharge into the offsite ditch before it combines on the north side of NE 122nd Street, therefore, is 1.22 cfs + 0.15 cfs, or *1.37 cfs*.

The 25 year discharge for the detained Beuca Property is 0.30 cfs. Documentation was not available at the time of this report for the two additional subdivisions to the west but they are similar in size to Beuca so a conservative assumption of 0.5 cfs was made for each with a combined flow at the point of compliance with the south side of NE 122^{nd} Street of 1.30 cfs. Therefore, the total anticipated flow in the downstream portion of the ditch after convergence with all upstream development area is 2.67 cfs (1.37 cfs + 1.30 cfs), well below the calculated capacity of 6.99 cfs or 9.5 cfs shown above.

In all cases checked, the capacity of the offsite ditch at an assumed flow depth of 6" is more than adequate for the anticipated fully developed flows tributary to the ditch, including a minimum 18" freeboard including the extension of the ditch toward NE 124th Street on the east side of 162nd Avenue NE.

The capacity of the downstream culverts were also examined. The plugged culverts in Exhibits C and D will be cleaned out by the developer prior to construction of the plat. The 2.67 cfs will produce the headwater depth will be about 1.1 feet based on Figure 4.3.1.B shown on the following page. Therefore, the 12-inch diameter culvert will be flowing full but not overtop the existing driveway.

FIGURE 4.3.1.B HEADWATER DEPTH FOR SMOOTH INTERIOR PIPE CULVERTS WITH INLET CONTROL

2009 Surface Water Design Manual

1/9/2009

4. Flow Control and Water Quality Facility Analysis and Design

Design Standards

The detention / water quality facilities will be designed per the Washington State Department of Ecology's Stormwater Management Manual for Western Washington, February 2005 Edition (DOE Manual) and the City of Redmond Clearing, Grading, and Stormwater Management Technical Notebook Issue 6.

The drainage analysis for flow control and water quality treatment design was modeled using the King County Runoff Time Series (KCRTS) software as allowed per Chapter 2.1.1 within Volume III of the 2005 DOE Manual and WWHM software. The vault will match developed discharge durations to 50% of the pre-developed 2-year peak flow to the full 50-year peak flow and provide dead storage

The site is located in the Sea-Tac rainfall region with a location scale factor of 1.0. Per the NRCS Soil Survey, the site soils are entirely Alderwood gravelly sandy loam, (AgC), KCRTS group Till and Hydrologic Group C.

A. Pre-developed Conditions

The existing basin boundary area is defined as that area that will be improved through development of the subject property. The subject property is approximately 3.59 acres in size and consists of 1 home with associated outbuildings and landscaping. The site is comprised entirely in one drainage basin, flowing northeast to southwest.

Pre-developed conditions for the project area was analyzed assuming 100% pervious ground cover consisting of forested land cover as defined in Section 2.3, pg 8, in the Technical Notebook under the definition of "Pre-developed condition." Due to topographic constraints, a portion of the entry road, approximately 0.08 acres of 166th Place NE and the frontage will not drain to the vault. Therefore, an equivalent amount of existing offsite area will be treated in in lieu of this area.

All upstream offsite area was modeled as existing conditions consisting of either forest, grass or impervious area. The upstream areas consist of:

- *Upstream Area North of NE 123rd Way*The 0.47 acres of forest and 0.14 acres of landscaping is from a single home (fully dispersed through the existing forested area), the preserved Tract D, and a portion of lots 7-10 and Tract E of the Wexford Glen development.
- Upstream Area NE 123rd Way
 There is approximately 0.15 ac of ROW from NE 123rd Way in the Wexford development that currently discharge through a flow spreader on the project site.

- Upstream Area Between NE 122nd Street and NE 123rd Way
 The 0.66 acres of landscaping are from the back yards of Lots 11 through 16 along with Tracts B and C of the Wexford Glen development that is located east of the project site.
- Existing Pavement Collected along NE 122nd Street

 There is 0.05 acres of existing pavement from NE 122nd Street that will drain to the vault as a result of completed the frontage improvements.

See Table 4-1 and Figure 4-1: Pre-Developed Conditions for a summary of the pre-developed areas.

Table 4-1: Pre-Developed Conditions Areas

B. Developed Conditions

Proposed development of the property will include the demolition of all structures on the property and construction of 15 single-family units (1 duplex) on 14 lots, along with associated roadway, utilities, open space, and drainage detention and treatment. Frontage improvements along NE 122nd Street and 166th Place NE and ROW improvements within the offsite NE 123rd Place will also be included as part of the development.

A single detention vault will be located in Tract A near the southwest corner of the property and designed per Redmond's design criteria. The detained flows will then be conveyed west to NE 122nd Street and into the existing ditch system located on the north side of NE 122nd Street or into the proposed tight line pipe system to be constructed as part of the Shadow Creek development immediately west of the Beuca Property project.

The offsite area assumptions are the same as the pre-developed conditions and the impervious coverage calculations for the developed site are delineated below.

- Impervious Coverage for the Proposed/Existing ROW
 The impervious coverage within the ROWs was determined in CAD
- *Impervious Coverage for the Proposed Access Tract*The impervious coverage within the proposed access tracts was assumed to be 100%.
- Impervious Coverage for Open Space / Drainage Tracts

 The impervious coverage within the open space/drainage tracts was assumed to be 20%.
- Impervious Coverage for the Lots

 The impervious coverage within the lots areas are determined to be 80% of the allowable impervious area per zoning code. The project is in R-3 zoning, which is allowed 60% impervious coverage. With a total lot area of 2.15 acres, the total lot impervious coverage is 2.12 acres * 80% * 60% = 1.02 acres.

See Table 4-2 and Figure 4-2: Developed Conditions for a summary of the developed conditions areas.

Table 4-2: Developed Conditions Areas

C. Detention Calculations

The 82 x 50 foot (inner dimensions) detention vault will be located near the south west property boundary in Tract A and has 9.2 feet of live storage. Refer to the end of the section for the full KCRTS output.

```
KCRTS Vault Calculation
         Type of Facility: Detention Vault
                                          ft
         Facility Length:
                                   82.00
          Facility Width:
                                   51.00
                                          ft
            Facility Area:
                                 4182.
                                          sq. ft
                                    9.00
Effective Storage Depth:
                                          ft
       Stage 0 Elevation:
                                  279.50
                                          ft
          Storage Volume:
                               37638.
                                          cu. ft
               Riser Head:
                                    9.00
                                          ft
          Riser Diameter:
                                   12.00
                                          inches
      Number of orifices:
                                    3
                                        Full Head

          Top Notch Weir: None
    Outflow Rating Curve: None
```

The proposed detention vault includes a three orifice control structure. The first orifice is 1 1/8 inch diameter and is at the bottom of the riser. The second orifice is 5.3 feet above the live/dead interface elevation and is 1-5/8 inches in diameter. The third orifice is 6.9 feet above the live /dead interface elevation and is 1-1/2 inch in diameter. The proposed vault will have a storage volume of 38,501 cubic feet at 9.2 feet of live storage.

Hyd	Inflow	Outflow		Peal	k	Storag	ie
		Target	Calc	Stage	Elev	(Cu-Ft)	(Ac-Ft)
1	1.50	*****	1.26	9.21	288.71	38501.	0.884
2	0.73	*****	0.33	8.99	288.49	37608.	0.863
3	0.72	0.30	0.26	7.71	287.21	32264.	0.741
4	0.88	*****	0.22	7.21	286.71	30159.	0.692
5	0.77	*****	0.18	6.91	286.41	28900.	0.663
6	0.45	0.17	0.11	5.53	285.03	23110.	0.531
7	0.55	*****	0.07	4.54	284.04	18972.	0.436
8	0.55	*****	0.06	2.72	282.22	11382.	0.261

The 2-year target outflow is 0.17 cfs and the vault will release 0.11 cfs. The 10-year target outflow is 0.30 cfs and the vault will release 0.26 cfs. Both the 2-year and 10-year vault release rates are below the pre-developed targets. See Figure 4-3 Flow Frequency Analysis below.

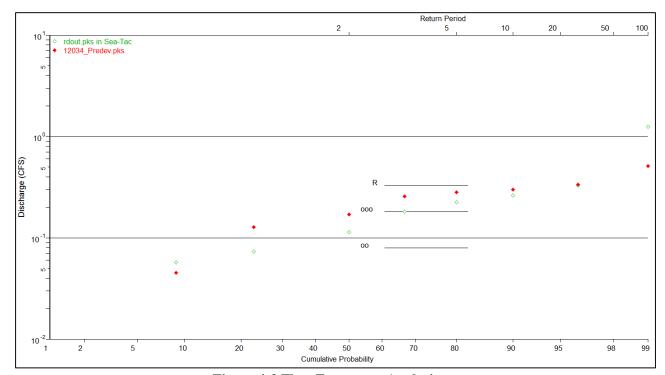

Figure 4-3 Flow Frequency Analysis

The flow duration comparison analysis results for the provided detention vault are shown below in Figure 4-4 Flow Durations Analysis. There is less than 10% excursion between the 2-year and 50-year release rate and the curve is entirely under the target curve for the required range of 50% 2-year to 2-year. Therefore, the proposed detention facility meets the flow duration requirement.

Maximum positive excursion = 0.022 cfs ( 7.8%)
occurring at 0.287 cfs on the Base Data:12034_predev.tsf
and at 0.310 cfs on the New Data:rdout.tsf
Maximum negative excursion = 0.011 cfs (-12.4%)
occurring at 0.092 cfs on the Base Data:12034_predev.tsf
and at 0.081 cfs on the New Data:rdout.tsf
```

D. Water Quality Calculations

Basic Treatment is required for the project site and a combined detention/wetpool vault will be designed and located near the southwest property boundary. Per page 10-4 in Volume V of the 2005 Stormwater Management Manual for Western Washington, basic water quality treatment volume is defined as the volume of runoff from the water quality design storm – the 6-month, 24-hour storm event. Per page 4-1 in Volume V of the 2005 Stormwater Management Manual for Western Washington, the 6-month, 24-hour precipitation amount is assumed to be 72% - 2-year, 24-hour amount.

The drainage analysis for water quality sizing was modeled using WaterWorks hydrology software utilizing SBUH methodology. The proposed vault will be utilized for both detention and water quality treatment.

The precipitation rates used for this analysis are as follows:

6-month, 24-hour storm (72% 2-year, 24-hour storm)
$$\rightarrow$$
 1.3 in. 2-year, 24-hour storm \rightarrow 1.8 in.

DEVELOPED AND		Pervious/		
UPSTREAM		Impervious		
TRIBUTARY CONDITIONS	Total Area = 4.77 acres	Areas		CN (avg)
GROUND COVER	AREA(acre)		CN	
Forest	0.47		73	
Lawn (Landscaping)	2.43	2.90	86	83.89
Impervious	2.02	2.02	98	98
Time of concentration	Assumed			10 min.

The required volume of dead storage for the developed basin is equal to 11,059 cubic feet. See WaterWorks basin summary report below. Four feet of dead storage will be provided in Cell 1 and 2.5 feet of storage will be provided in Cell 2 for a total dead storage volume of 11,706 cubic feet.

5. Conveyance System and Analysis and Design

Conveyance design and analysis will be provided at the final design phase of the project.

6. Special Reports and Studies

The reports listed are provided spearately. Any additional special reports and studies will be provided at final design.

Geotechnical Report

Prepared for: Beuca Plat

Prepared by: Theodore J. Schepper, PE

Dated: April 27, 2012 Terra Associates, Inc.

12525 Willows Road, Suite 101

Kirkland, WA 98034

➤ Infiltration Feasibility (LID Assessment)

Prepared for: Beuca Plat

Prepared by: Carolyn Decker, PE

Dated: September 7, 2012 Terra Associates, Inc.

Kirkland, WA 98034

PROJECT LID FEASIBILITY

Site Soils

Based on a review of the Beuca Plat project, the soils on site "consist of glacially consolidated silty sand with gravel (glacial till)." LID elements constructed on till soils do not typically perform well due to their reliance on infiltration (glacial till soils, unless weathered, typically have low permeability). However, the Puget Sound Partnership's *LID Technical Guidance Manual for Puget Sound* notes that:

- 1) Bioretention facilities and permeable pavements can perform adequately in soils exhibiting minimum infiltration rates as low as 0.1 in/hr; and
- 2) Hydrologic soil groups A, B and C are considered to be appropriate for implementing LID elements.

The project Geotechnical Engineer (Terra Associates) conducted site observations and analyses to determine the feasibility of the on-site soils supporting infiltration. The recommendation from the Geotechnical Engineer is that on lot infiltration is not feasible for the project site (refer to the "Infiltration Feasibility" letter included at the back of this Section). This recommendation includes roof infiltration and bioretention BMPs.

Based on the above discussion and corresponding Geotechnical Engineer recommendations, typical bioretention facilities, roof infiltration and permeable pavements are not feasible on the Beuca Plat project.

Wellhead Protection Zones

The City of Redmond has identified four (4) Wellhead Protection Zones throughout the City in order to help manage the variable, and often shallow, groundwater impacts to land development activities. The City Wellhead Protection Zone map in the project vicinity is included in Section 1 of this report.

The Beuca Plat project is located in Wellhead Protection Zone 4. Once identified on the City map, the applicable Wellhead Protection Zone sets or modifies two key design parameters including:

- Soil classification for hydrologic analysis (detention facility sizing)
- Infiltration limitations

The Beuca Plat project, therefore, will be limited in any application of LID features that rely on infiltration. Flow control credits are provided based on clear demonstration of the site suitability criteria for the soils. Infiltration within Wellhead Protection Zone 4 is allowed by the City of Redmond for all non-pollution generating impervious surfaces or pollution generating impervious surfaces following Enhanced Treatment.

Hydrology

One of the primary considerations for applying and integrating LID elements into a project is the hydrologic impact. Since a primary objective of sustainable site design and LID is to better mimic the natural hydrologic cycle, the overall impact a project has on its environment is theoretically reduced by managing the stormwater very near to the point where it falls.

The City of Redmond provides some direct benefit to the hydrologic modeling (detention facility sizing), required of a project, when certain LID elements are proposed. The Beuca Plat project would benefit from implementation of LID elements in the hydrologic modeling of the proposed detention facility.

Feasible Project-specific LID Elements

Based on the site assessment and geotechnical recommendations no LID elements are feasible or proposed.

7. Other Permits

Additional permits will be addressed during the final design phase and may include the following:

- NPDES Permit
- Right-Of-Way Use Permit
- Forest Practices Permit

8. CSWPPP Analysis and Design

TESC calculations and design will be provided at the final design phase of the project.

9. Bond Quantities, Facility Summaries and Declaration of Covenant

An engineering cost estimate will be provided prior to final engineering approval for this project.

10. Operations and Maintenance Manual

An operations and maintenance manual will be provided for all storm water facilities at the final design phase of the project.
